Exposing single-walled carbon nanotubes to room-temperature UV-generated ozone leads to an irreversible increase in their electrical resistance. We demonstrate that the increased resistance is due to ozone oxidation on the sidewalls of the nanotubes rather than at the end caps.

When $\cdot\text{OH}$ was quenched, O₃ had no observable effects on the unfunctionalized aromatic rings, which are more predominant on reduced GO and graphene. Microscopy analyses showed that ozonation led to crumpling of GO nanosheets, truncation of GO edges, formation of holes (diameter = 5–15 nm), and production of small-sized graphenic fragments.

To produce pure drinking water, the removal of NOM is a prior task in modern water treatment. Ozone, like any other oxidant, seldom achieves a complete mineralisation of NOM. Organic matter is partly oxidized and becoming more easily biodegradable. This results in a higher amount of BDOC (Biodegradable DOC).
