The Gabriel synthesis is an organic reaction used to convert an alkyl halide to a primary amine using phthalimide with base and followed by hydrazine. The reaction begins with the deprotonation of the phthalimide which then attacks the alkyl halide in an S_N2 fashion to give an N-alkylphthalimide intermediate. The intermediate is then cleaved by hydrazine in a series of steps that end with the liberation of the final primary amine product and phthalhydrazide by-product.

Gabriel Phthalimide Synthesis Mechanism -
Explanation and ...

Gabriel Synthesis Potassium phthalimide is a -NH₂-synthon which allows the preparation of primary amines by reaction with alkyl halides. After alkylation, the phthalimide is not nucleophilic and does not react anymore. Product is cleaved by reaction with base or hydrazine, which leads to a stable cyclic product.

The Gabriel synthesis is a chemical reaction that transforms primary alkyl halides into primary amines. Traditionally, the reaction uses potassium phthalimide. The reaction is named after the German chemist Siegmund Gabriel. The Gabriel reaction has been generalized to include the alkylation of sulfonamides and imides, followed by deprotection, to obtain amines. The alkylation of ammonia is often an unselective and inefficient route to amines. In the Gabriel method, phthalimide anion is employed

This reaction is known as the Gabriel synthesis of primary amine. It is found that under basic conditions for the hydrolysis of N -alkyl phthalimide, the second step is the rate-limiting step. The hydrolysis has been modified by using hydrazine. The reaction is generally used for the synthesis of aliphatic primary amines.

Phthalimide is the organic compound with the formula $C_6H_4(CO)_2NH$. It is the imide derivative of phthalic anhydride. It is a sublimable white solid that is slightly soluble in water but more so upon addition of base. It is used as a precursor to other organic compounds as a masked source of ammonia.
